Dental Caries Events by Exposure to Fluoridated Water — A Survival Analysis

Pingzhou Liu, John Spencer, Loc Do and Jason Armfield
ARCPOH, School of Dentistry
The University of Adelaide

Background

- Water fluoridation is an important public health measure
- Water fluoridation prevents dental caries*
- Epidemiological investigations of dental caries are commonly based on cross-sectional designs
- ARCPOH’s Child Fluoride Study Mark I (CFS - I) data provide an opportunity to carry out a longitudinal study**

Objective

To examine the association of lifetime exposure to fluoridated water with dental caries events on the occlusal surface of first permanent molar teeth.
Clinical data were obtained from a cohort 9,485 SA children and 10,109 Qld children recruited through the school dental services in 1991/1992 and followed until the end of 1997.

A baseline questionnaire to parents provided information on residential and fluoride history and other confounders.
Methods (I)

For each individual child’s life span

- The percentage of lifetime exposure to fluoridated water (FW) was estimated between DOB and Baseline.
- Eruption time $E$ of first permanent molar teeth was estimated.
- Time of a caries event ($D$) on the occlusal surfaces of 1st permanent molars was estimated.
- Duration (months) to each caries event or duration of exposure to a risk of caries.
Methods (II)

Survival analysis techniques using a Cox regression model were used to estimate the probability of dental caries events, the risk ratio and their association with explanatory variables.

<sup>†</sup> Adjusted by state, brushing frequency and household income
Survival function for percent lifetime exposure to FW*

* Adjusted by State, brushing frequency and household income
Results

The hazard of a dental caries event among children with zero exposure was 2.4 times that of children with 100% lifetime exposure to fluoridated water (p<0.001).

With control of covariates (State, brushing frequency, income), the hazard of a dental caries event on the occlusal surface of first permanent molars for zero exposure was still 1.8 times that of 100% exposure to fluoridated water (p<0.001).
Conclusion

Exposure to fluoridated water has a strong protective effect on the risk of developing caries on the occlusal surface of 1st permanent molars of children.
